Air Pollution Meteorology

Meteorology’s Effect on Air Quality
Meteorological Products and Examples
Overview (1 of 2)

- Meteorological processes that influence air quality
  - Sunlight
  - Horizontal dispersion
  - Vertical mixing
  - Transport
  - Clouds and precipitation
  - Temperature and humidity
- Large scale to local scale
Air Masses and Fronts (1 of 3)

Fronts are regions where an atmospheric variable (temperature, dew point, etc.) changes rapidly across a small horizontal distance and divides air masses.

- Cold, dry, Usually Clean
- Warm, moist, Often Polluted
- Cool, Occasionally Polluted
Air Masses and Fronts (2 of 3)

Example

- Fronts and air masses can cause rapid changes in air quality levels within a few hours of passage, particularly cold fronts.
- Weak fronts can have little to no impact of their own; however, enhanced convection that occurs near them can improve air pollution.
- A stationary front positioned near an area is often associated with high PM$_{2.5}$ levels because of light winds and no mass transfer.
Air Masses and Fronts (3 of 3)

Minneapolis-St. Paul, Minnesota, USA

Section 10 – Air Pollution Meteorology
Temperature Inversions (2 of 3)

Inversions are important because they suppress vertical dispersion of pollution and often trap pollution near the surface where we live.

Vertical temperature profile

Inversion

Warm

Cool
Temperature Inversions (3 of 3)

• Subsidence
  – Created by sinking air associated with ridges
  – Can limit daytime mixing depth and plays important role in daytime pollutant concentrations

• Nocturnal or radiation
  – Created by cooling ground at night
  – Strongest with clear skies, light winds, and long nights
  – Can trap emissions, released during the overnight hours, close to the ground (e.g., wood smoke)

• Advection
  – Created when warm air aloft moves over cooler air below
  – Can occur ahead of an approaching cold front
  – Can cause poor air quality, despite the lack of an aloft ridge
Stability

• Stability is associated with how air parcels behave once they are displaced vertically from their initial positions.

• Three types
  – **Positive stability** implies that a displaced air parcel will return to its initial position; associated with **high pollution**
  – **Neutral stability** implies that a displaced air parcel will remain at its new position; associated with **moderate pollution**
  – **Negative stability**, or instability, means that a displaced air parcel will continue to accelerate away from its rest position; associated with **low pollution**
Stability

Example of positive stability and negative stability – influence on a chimney plume (APM, Latrobe Valley, Victoria, Australia)

Paper Mill plume after Sunrise

Unstable
Inversions, Stability, and Mixing (1 of 4)

Pollutants mix into a large volume resulting in low pollution levels

Weak and high inversion

Pollutants mix into a smaller volume resulting in high pollution levels

Strong and low inversion

RL = Residual Layer
CBL = Convective Boundary Layer
NBL = Nocturnal Boundary Layer

Surface-based mixing depth

Surface-based vertical mixing

Winds

Horizontal dispersion and transport

- **Synoptic-scale**
  - Winds are driven by large high- and low-pressure systems

- **Meso- and local scale**
  - Create stagnation and recirculation
  - Local flows are often difficult for weather models to predict but can be predicted by forecasters with knowledge of the area

- **Types**
  - Land/sea or lake breeze
  - Mountain/valley
  - Terrain forced
  - Diurnal cycles

- **Surface vs. boundary layer**
  - Transport at different vertical levels
  - Mixing during the day affects winds
Winds – Dispersion

How do winds affect pollution?

- Disperse pollutants – the spreading of atmospheric constituents
- Dispersion is a dilution process
  - Molecular diffusion (not efficient)
  - Atmospheric turbulence
    - Mechanical
    - Shear
    - Buoyancy (convective)

Source: meted.ucar.edu/dispersion/basics/navmenu0.htm

Section 10 – Air Pollution Meteorology
Winds – Transport

How do winds affect pollution?

• Pollutant transport – movement of pollutants from one area to another by the wind

• Types
  – Neighborhood scale: monitor to monitor
  – Regional scale: city to city and state to state
  – National scale: country to country.
  – Global scale: continent to continent

Section 10 – Air Pollution Meteorology
Transport – Regional Scale (3 of 5)

Example schematic showing components of peak ozone in Salt Lake City. The transport direction has no significance.
High pollutant concentrations upstream can be transported into a different area and can cause substantial increases in air quality concentrations than would otherwise occur.

Chinkin et. al., 2003
Transport – National Scale

Images from http://rapidfire.sci.gsfc.nasa.gov

Section 10 – Air Pollution Meteorology
Synoptic-Scale Winds and Fire

The most devastating fires in Australia in recent years occurred during periods of strong hot winds originating at the centre of the continent after a prolonged period of low rainfall.
Transport – Global Scale

Asian dust transport across the Pacific

Section 10 – Air Pollution Meteorology
How do winds affect pollution?

- Create pollution – wind-blown dust
- Two requirements
  - Dusty land/soil
  - Winds 7 m/s can loft dust

Section 10 – Air Pollution Meteorology
Smoke

- Smoke plumes (orange) from biomass fires over Borneo in 1998 were transported southwestward by the prevailing NE Trade winds prevalent over the region at that time of the year.

- Drought, caused by El Niño, resulted in increased biomass burning.
Clouds and Precipitation (1 of 3)

• Clouds form when the air becomes saturated
  – Adding water vapor
  – Cooling air

• Many processes add water vapor or cool air
  – Rising motion
    • Trough
    • Daytime heating
    • Cold front undercutting warm air (or vice versa)
    • Orographic
      – Air in contact with cooler surface
      – Air moving over water
      – Others
Clouds and Precipitation (2 of 3)

- Clouds and fog can increase the conversion of sulfur dioxide to sulfate from 1% per hour to 50% per hour.
- Clouds reduce ozone photochemistry.
- Precipitation removes PM$_{10}$ but has little direct impact on PM$_{2.5}$.
- Convective clouds can vent pollution from the boundary layer under stable conditions.
- Clouds reduce surface heating and ability to break inversion.
- Clouds delay NO$_2$ photolysis.

Heating and Winds – Local Scale

Convective Mixing of Plumes

Mixed-layer height controls ground-level concentrations

Chimney as source of pollution
Heating and Winds – Local Scale

Seabreeze Fumigation

- Advection of cool marine air inland by the sea breeze. The air is heated from below by the warm land surface.
- Formation of the Thermal Internal Boundary Layer (TIBL).
- Fumigation occurs when pollutants released into the stable marine air mass encounter the TIBL boundary, and are mixed downward to the Earth’s surface by convective motion.
- The stable air mass above the TIBL acts as a "lid," trapping pollutants released into the marine air, in the unstable TIBL.
Summary
Meteorology Associated with Poor AQ

Ridge of High Pressure

Sinking Motion

Warms, Dries, and Stabilizes

Creates Temperature Inversion

Reduces Vertical Mixing

Clear Skies

Photochemistry

Surface High

Local Flows and/or Light Winds, Possible Transport

Stagnation/Recirculation

Poor Air Quality

Section 10 – Air Pollution Meteorology
Summary
Meteorology Associated with Good AQ

Trough of Low Pressure

Rising Motion

Cools, Moistens, and Destabilizes

No Temperature Inversion

Cloudy Skies

Reduces Photochemistry (but may enhance PM$_{2.5}$ chemistry)

Enhances Vertical Mixing

Surface Low

Moderate to Strong Winds (Transport)

Horizontal Dispersion

Good Air Quality

Section 10 – Air Pollution Meteorology
Key Weather Features – Summary

- Upper-air and surface patterns
- Fronts and air masses
- Inversions, stability, and mixing
- Winds
- Clouds
- Precipitation
- Recirculation, especially on coasts, in complex terrain can lead to the worst air pollution events.
Other Useful Products

- 850-mb temperature and 700-mb vertical velocity charts
- HYSPLIT trajectories
- Satellite data
- Ground-based remote sensors (sodar, radar profiler, lidar)
Using Weather Charts to Help Forecast Air Quality

- Depict upper-air meteorological patterns as a horizontal slice of the atmosphere
- Show forecasted meteorological variables at a particular time on a particular pressure level
Weather Charts – Aloft

- 850-mb temperature
  - Good indicator of stability
  - Boundary layer transport winds

- 700-mb vertical velocity
  - Downward vertical motion (negative on charts shown here) indicates stable conditions and is associated with poor air quality
  - Upward vertical motion (positive on charts shown here) indicates unstable conditions and is associated with good air quality
Weather Charts
Predicting Surface and Aloft Patterns

850-mb heights and temperature

700-mb heights and vertical velocity

Section 10 – Air Pollution Meteorology
Weather Charts
850-mb Temperature Example

- Warm 850-mb temperatures can stabilize the atmosphere, which can lead to poor air quality by reducing vertical mixing.
- Cool 850-mb temperatures can destabilize the atmosphere, which can lead to good air quality by enhancing vertical mixing.

PM$_{2.5}$ 24-hr averages (AQI) from www.airnow.gov

Section 10 – Air Pollution Meteorology
Weather Charts
700-mb Vertical Velocity Example

Downward vertical motion stabilizes the atmosphere which can lead to poor air quality

Upward vertical motion destabilizes the atmosphere which can lead to good air quality even under a ridge

Transport Tool – HYSPLIT (1 of 3)

Hybrid Single-Particle Lagrangian Integrated Trajectory Model (HYSPLIT)
• Uses meteorological model data to estimate trajectories and dispersion in the past or future
• Run on NOAA’s Realtime Environmental and Display System (READY) web site
• Can run locally with gridded model data
• Intended for meso- and syntopic scale transport

Section 10 – Air Pollution Meteorology
Satellite (1 of 4)

- Satellite data can help forecasters
  - Estimate aerosol concentrations in areas without continuous PM\textsubscript{2.5} monitors
  - Track aerosols from
    - Regional haze episodes
    - Wildfires
  - Estimate upwind PM\textsubscript{2.5} concentrations or aerosol loading
- Aerosol optical depth provides this information
• Aerosol optical depth (AOD)
  – A satellite-derived measure of light extinction through the atmosphere
  – Proportional to the number of particles in the atmospheric column
Satellite (3 of 4)

- Factors for forecasters to consider when using AOD products
  - Clouds: AOD can only be computed when skies are clear.
  - Vertical resolution: AOD does not differentiate between particles aloft and particles near the ground.
  - Surface/land use: The AOD algorithm works best over flat, dark terrain.
  - Aerosol type: The AOD algorithm works best when aerosols are spherical. Irregular particles do not scatter light well.
  - Availability: AOD data can only be computed during daylight hours.
Satellite (4 of 4)

• The AOD algorithm does well detecting
  – Spherical particles that scatter light well such as sulfates and nitrates
  – Volatile organic compounds, a component of smoke

• The AOD algorithm does not do well detecting
  – Dust particles are irregularly shaped and do not scatter light well; because of this, they are not captured well by the AOD algorithm.
  – Black carbon, a large component of smoke
Satellite –
Forecasting Applications (1 of 5)

• Goal is to show
  – How AOD data can be used to identify smoke from large fires
  – How to predict where the smoke will be transported
  – How to evaluate whether the smoke is mixing to the surface

• Considerations
  – The AOD can be used to detect smoke from large fires well
  – AOD tracks aerosols after they cannot be seen on visible satellite imagery
  – Very dense smoke can be mistaken for clouds and, consequently, not be included in the AOD algorithm
Satellite – Forecasting Applications (2 of 5)

• The B and B Complex Fire, Oregon (August 19 to September 26, 2003)
  – Burned 91,000 acres
  – The MODIS (Terra) visible image (left) shows the smoke plume spreading northeast from the fire on September 4, 2003
  – The AOD plot (right) shows the smoke plume well; the area of black inside the red plume is where the algorithm failed due to dense smoke

• Key forecast questions:
  – Where is it going?
  – Is it mixing down?
Satellite – Forecasting Applications (3 of 5)

- Need to determine mixing
- Compare correlations between AOD and observed PM$_{2.5}$
  - Moderate AQI levels on the AIRNow PM$_{2.5}$ map from September 4, 2003, in eastern Washington State (center)
  - PM$_{2.5}$ sites collocated with the high AOD values show poor correlation with the AOD on September 4 and on previous days.
  - This indicates that the aerosols may not all be mixing down to the surface.
Satellite – Forecasting Applications (4 of 5)

- Trajectory plots indicate transport of smoke into the Northern Plains
- Forecasters should analyze mixing characteristics in the Northern Plains to determine potential smoke impact
Satellite – Forecasting Applications (5 of 5)

• Static AOD plots can be used to assess transport
• The loop below shows the progression of the high AOD from the Pacific Northwest into the Ohio Valley from September 4 through September 10, 2003
**Lidar** (1 of 3)

- **Light Detection And Ranging (LIDAR)** transmits light out to a target. Some of this light is reflected or scattered back to the lidar.
- Lidar can measure
  - Winds
  - Turbulence
  - Clouds
  - Aerosols
  - Water vapor
  - Other atmospheric constituents such as ozone and carbon dioxide
Lidar (2 of 3)

- Lidar is useful for forecasting because it can vertically resolve ozone and aerosol layers.
Lidar shows a layer of smoke at about 3 km altitude.
Smoke evident on visible satellite image.
No unusually high PM$_{2.5}$ at the surface.
For forecasting, run forward trajectories at 3 km to determine movement of smoke layer.
Determine if vertical mixing will bring particles down to the surface.
Radar Wind Profiler – Winds

- Used to understand processes and help forecast
- Provides
  - Continuous winds
  - Continuous temperature profiles
  - Continuous mixing

Radar profiler wind data at Visalia on August 9, 1998, showing the nocturnal jet, convective boundary layer (CBL), and eddy flow. This wind pattern was observed on the majority of the episode days (MacDonald et al., 1999).
Upper-air winds on July 14, 1995, at 0300 EST, used to locate the low-level jet during an air pollution episode

Section 10 – Air Pollution Meteorology
The nocturnal jet can transport air pollution over several hundred kilometers during the overnight hours. This aloft pollution mixes to the surface the following day. The RWP data can be used to diagnose the existence and strength of the nocturnal jet.
